What is superconducting magnetic energy storage (SMES)? Superconducting magnetic energy storage (SMES) systems store energy in the magnetic field created by the flow of direct current in a superconducting coil that has been cryogenically cooled to a temperature below its superconducting critical temperature. This use of superconducting coils to store magnetic energy was invented by M. Ferrier in . Why do superconducting materials have no energy storage loss? Superconducting materials have zero electrical resistance when cooled below their critical temperature--this is why SMES systems have no energy storage decay or storage loss, unlike other storage methods. Does room temperature superconductivity exist? Another point merits mention. Over recent decades there have been reports of signals of possible room temperature superconductivity, usually in resistance or susceptibility measurements, which is the most straightforward evidence of superconductivity. The samples were invariably polycrystalline, multiphase, or disordered to the point of amorphous. Why do superconductors have a high critical temperature? A substance with a high critical temperature will generally have a higher critical current at low temperature than a superconductor with a lower critical temperature. This higher critical current will raise the energy storage quadratically, which may make SMES and other industrial applications of superconductors cost-effective.
